## Lecture 35 — Concurrency Control Implementation

Jeff Zarnett jzarnett@uwaterloo.ca

Department of Electrical and Computer Engineering University of Waterloo

March 9, 2024

MTE 241 Spring 2024 1/40

## Things Got Weird

We talked a lot about why we need concurrency control mechanisms.

We even spent a little time discussing how they might work.

But...

MTE 241 Spring 2024 2/40

#### LA LA LA NOT LISTENING

One possible solution that works in an embedded system or very simple OS is disabling interrupts.

Crude and permits bad behaviour...

Does not work for multiple processors.

MTE 241 Spring 2024 3/40

### **Test-and-Set**

Where we landed was the use of test-and-set!

A special machine instruction that is performed in a single instruction cycle and is therefore not interruptible.

MTE 241 Spring 2024 4/40

# **Testing and Setting**

```
boolean test_and_set( int* i ) {
   if ( *i == 0 ) {
     *i = 1;
     return true;
   } else {
     return false;
   }
}
```

#### An example of the code that uses the test\_and\_set routine:

```
while ( !test_and_set( busy ) ) {
   /* Wait for my turn */
}
/* critical section */
busy = 0;
```

MTE 241 Spring 2024 5/40

# **Testing and Setting**

No matter how many threads are executing the code above concurrently, only one will succeed in actually setting the value to 1.

You will notice here that the assignment of busy = 0 doesn't use something like a test-and-clear instruction or similar.

Is that assignment okay? Grudgingly!

MTE 241 Spring 2024 6/40

# Compare-and-Swap

Test-and-Set does not work for the general, counting semaphore.

Alternative: compare-and-swap (or compare-and-exchange).

MTE 241 Spring 2024 7/40

## **Comparing and Swapping**

```
int compare_and_swap( int * value, int old_value, int new_value ) {
  if ( *value == old_value ) {
    *value = new_value;
    return old_value;
  }
  return *value;
}
```

MTE 241 Spring 2024 8 / 40

And to make use of it in trying to decrement a semaphore:

```
int old = 1;
while (true) {
  int actual = compare_and_swap( sem, old, old - 1 );
  if ( actual == old ) {
   old = old - 1:
   break ·
  } else {
   old = actual:
  WAIT FOR OUR TURN */
   critical section */
while (true) {
  int actual = compare_and_swap( sem, old, old + 1 );
  if ( actual == old ) {
    break:
  } else {
   old = actual:
```

MTE 241 Spring 2024 9/40

## It Took How Many Tries?

We will eventually succeed, even if it takes an arbitrary amount of time.

It might be possible for a thread to be so unlucky it never gets a turn, but let's just say that this does not happen.

The initial guess for old can certainly be wrong; the initial attempt to set it will fail and we'll get the correct value.

Need to use CAS for decrementing also!

MTE 241 Spring 2024 10 / 40

# Wait, Why?

Alternative: if there is appropriate hardware support, do an atomic increment or atomic decrement.

That prevents a scenario where multiple attempts are necessary to get the value.

MTE 241 Spring 2024 11/40

# **Terms and Conditions Apply**

There is the big WAIT FOR OUR TURN comment there...

Uh... how do we wait for it?

MTE 241 Spring 2024 12/40

#### The Future is Now

Earlier: if we don't get the result we want, the OS blocks the thread.

No details were provided as to how that happens; just hand-waving.

When you leave things for tomorrow and tomorrow arrives

MTE 241 Spring 2024 13/40

## **Blocking and Unblocking**

So you want to lock a mutex or wait on a semaphore...

There was a system call; it had a TAS, CAS, or atomic operation.

If this was a trylock call, they don't get blocked; skip this section.

MTE 241 Spring 2024 14/40

Blocking a thread is easy for the operating system.

Change the status to be blocked and choose another thread to run.

MTE 241 Spring 2024 15/40

### **Blocked Threads Go Where?**

Marking a thread as blocked or moving it to a "blocked" queue is insufficient.

We will need some way of knowing that this thread is blocked on the particular semaphore or mutex it was accessing.

Maybe the mutex/semaphore has its own queue?

MTE 241 Spring 2024 16 / 40

## **Unblocking**

Whichever thread did lock the mutex will want to unlock it or some thread will post on a semaphore.

Counting semaphore: always increase counter, unblock a thread waiting.

Mutex: change the counter only if no thread waiting, otherwise unblock.

MTE 241 Spring 2024 17/40

# Who's Waiting?

This prompts immediately the question of what thread should be unblocked when an unlock or post event occurs.

Again, that's a scheduling decision, but you could choose a simple and "fair" approach of just taking the first thread in the queue.

This might not be optimal. Why?

MTE 241 Spring 2024 18 / 40

#### On the Other Hand

The first-come-first-served approach does prevent the possibility of starvation, as each thread will eventually get a turn.

But just basing it on priority may not be enough?

Could we try to detect deadlock risk?

MTE 241 Spring 2024 19 / 40

## Get to the Choppa

The thread that's unblocked is marked as ready to run again. Moved to ready queue?

And at this point it is a scheduling decision: which thread continues execution.

But we knew that from doing all this from the application developer point of view.

MTE 241 Spring 2024 20 / 40

## **Carry On Then**

When a thread is unblocked it resumes its execution at the return of the system call and will proceed as expected.

That was easier than expected!

MTE 241 Spring 2024 21/40

Previously: build up the RW lock using combo of semaphores/mutex.

It's likely more efficient to have a self-contained construct that meets the goal.

A simple counter is probably insufficient. Why?

MTE 241 Spring 2024 22/40

#### Counter

If the counter is currently 1, is that a reader or a writer thread?

So let's have two counters, shall we? One for readers and one for writers.

But things get interesting depending on whether you care about writer priority.

MTE 241 Spring 2024 23/40

# **Equality for All**

How should this work if we don't give priority to either side?

MTE 241 Spring 2024 24/40

#### **Two Counters?**

At first we might consider two counters; one for readers and one for writers.

If the readers counters is 7, is that seven readers currently in the room or seven readers waiting to enter?

It's hard to know and we'll need some more accounting.

MTE 241 Spring 2024 25/40

## I have a cunning plan...

We talked about the light bulb analogy for the way of understanding the reader-writer lock...

MTE 241 Spring 2024 26 / 40

## Use the Light Bulb

Idea: a boolean variable that says whether the lights are on.

Then a counter could be used to keep track of the number of readers currently in the room.

The reader-writers lock can have associated reader and writer queues.

MTE 241 Spring 2024 27/40

### **Reader Does What?**

Reader: try to set light switch from 0 to 1 with TAS.

If they succeeded, they're the first reader: proceed.

If they failed, why? Readers or writers?

MTE 241 Spring 2024 28 / 40

### **Reader Does What?**

When the reader is done, decrement.

If it falls to zero, unblock a writer if one waiting... Otherwise set light switch to 0.

MTE 241 Spring 2024 29 / 40

### Writer Does What?

If a writer wants to enter the room, try to change the light switch from 0 to 1.

If the writer succeeds, it can proceed.

If it fails, block the writer.

MTE 241 Spring 2024 30 / 40

### Writer Does What?

When the writer is done, unblock either all waiting readers or a writer.

Note that it's all the readers!

Can we prioritize writers here?

MTE 241 Spring 2024 31/40

# **Priority to Writers**

Yes, writers always choose writers at the end.

There is a risk of starvation – is that okay?

MTE 241 Spring 2024 32/40

## **Writer Priority**

That's not quite what we wanted.

Goal: when a writer is waiting, no new readers are allowed to enter the room.

How would we go about that?

MTE 241 Spring 2024 33/40

### **Writer Priority**

When a reader wants to enter the room, take a look at the state of the waiting queue for writers.

If there is one, even if we would normally let the reader proceed, block the reader thread.

MTE 241 Spring 2024 34/40

### Is This Atomic?

The logic requires us to try to change the light switch and also to maybe modify the counter and then decide based on that.

That's not atomic!

We may need a mutex internally here.

MTE 241 Spring 2024 35/40

# On the Right Track?

We discussed the implementation of a RW spinlock in Linux:

Counter	Flag	Interpretation
0	1	The spinlock is released and available.
0	0	The spinlock has been acquired for writing.
n (n > 0)	0	The spin lock has been acquired for reading by <i>n</i> threads.
n (n > 0)	1	Invalid state.

I'd say this validates our idea for how to implement RW Locks...

MTE 241 Spring 2024 36 / 40

### **Condition Variable**

Remember: different semantics...

Lost-wakeup problem, but also paired with a mutex.

When a wait happens, the thread must be holding a mutex.

Blocked for sure; release the mutex.

MTE 241 Spring 2024 37/40

# Signal or Broadcast

Signal may unblock a thread but it needs the mutex to continue.

Broadcast the same, but many threads... Each of which still needs the mutex!

MTE 241 Spring 2024 38 / 40

### No Internal Counter

Condition variables don't have or need an internal counter.

Yes, the lost-wakeup problem does exist but it's part of the spec.

It's not just a semaphore with broadcast.

MTE 241 Spring 2024 39 / 40

#### No Internal Counter

In many ways it would be wrong to have such a counter.

We cannot use a semaphore as the basis for a condition variable.

But this is simpler anyway so why would we want to?

MTE 241 Spring 2024 40 / 40
